

What is claimed is:

1. In a remodulator system, apparatus for controlling the bit rate of an output packet stream, comprising:

a source of an input transport packet stream;

5 an input packet buffer, coupled to the input transport packet stream source, for generating a status signal indicating whether the input packet buffer is: full, empty, or neither empty nor full;

an output packet stream generator, coupled to the input packet stream buffer, and responsive to an output clock signal, for generating the output packet stream in synchronism with the output clock signal,

a variable output clock signal generator, responsive to a control signal; and

a control signal generator, responsive to the status signal, and generating the control signal.

15 2. The system of claim 1 wherein:

the variable output clock signal generator is responsive to the control signal for varying the frequency of the output clock signal; and

the control signal generator comprises circuitry to generate the control signal to condition the variable output clock signal generator to increase its

20 frequency if the status signal indicates that the input packet buffer is full, and decrease its frequency if the status signal indicates that the input packet buffer is empty.

3. The system of claim 2 wherein:

25 the input packet buffer generates the status signal further indicating whether the input packet buffer is: nearly full, or nearly empty;

the control signal generator further comprises circuitry to generate the control signal to condition the variable output clock signal generator to increase its frequency if the status signal indicates that the input packet buffer is nearly full, and decrease its frequency if the status signal indicates that the input packet buffer is nearly empty.

0936228-09159

4. The system of claim 1 wherein:
the input transport packet stream contains null packets; and
if the status signal indicates that the input packet buffer is full, null
packets are deleted from the input transport packet buffer.

5

5. The system of claim 1 further comprising:
a source of additional packets; wherein:
the output packet stream generator comprises a multiplexer, coupled to
the input transport packet stream source and the additional packet source, for
10 combining packets from the input transport packet stream and additional packets
to generate the output packet stream.

09396228-091599

15

6. The system of claim 5 wherein if the status signal indicates that the input
packet buffer is empty, an additional packet is inserted into the output packet
stream.

20

7. The system of claim 5 wherein the source of additional packets comprises:
a source of packets representing auxiliary data; and
a source of null packets; and
the multiplexer inserts an auxiliary data packet into the output packet
stream as an additional packet if an auxiliary data packet is available, and inserts
a null packet into the output packet stream as an additional packet if an auxiliary
data packet is not available.

25

8. In a remodulator system, a method for controlling the bit rate of an output
packet stream, comprising the steps of:

30

providing a source of an input transport packet stream;
storing input packet from said source in an input packet buffer;
generating a status signal indicating whether the input packet buffer is:
full, empty, or neither empty nor full;
generating the output packet stream in synchronism with the output clock
signal;

generating a variable output clock signal in response to a control signal;
and
generating the control signal in response to the status signal.

5 9. The method of claim 8 wherein:

the frequency of the output clock signal varies in response to the control signal, and

the variable output clock signal increases in frequency if the status signal indicates that the input packet buffer is full, and decreases in frequency if the
10 status signal indicates that the input packet buffer is empty.

10. The method of claim 9 wherein:

the status signal further indicates whether the input packet buffer is:
nearly full, or nearly empty; and

15 the control signal conditions the variable output clock signal to increase its frequency if the status signal indicates that the input packet buffer is nearly full, and decrease its frequency if the status signal indicates that the input packet buffer is nearly empty.

20 11. The method of claim 8, wherein:

the input packet stream format is compatible with one of a QAM or QPSK modulation format; and

the output packet stream format is compatible with an 8-VSB or 16-VSB modulation format.

25

12. The method of claim 8, wherein:

the source of input transport packet stream represents auxiliary on-screen display (OSD) information.

30 13. The method of claim 8, wherein:

the input packet stream format is compatible with one of QAM, QPSK or VSB modulation formats; and

09396228-091599
665760-92296660

the output packet stream format is compatible with a different one of said QAM, QPSK or VSB modulation formats.
